5 Summary

The Advanced Encryption Standard

- ▶ Designed by Vincent Rijmen and Joan Daemen, under the name Rijndael and submitted to NIST's competition in 1998.
- ▶ Selected after a three year competition as the new standard.
- ▶ The cipher has an SP network structure.
- ▶ Block size — 128 bits, Key size — 128, 192, or 256 bits.
- ▶ Number of rounds depends on the key length (10/12/14, respectively).

The Advanced Encryption Standard

AES' Key Schedule Algorithm

AES has three key schedules. One for each key size.

- ▶ AES-128 ($Nk = 4$) and AES-192 ($Nk = 6$):

- 1 Initialize $W[0, \dots, Nk - 1]$ with the user supplied key.
- 2 For $i = Nk, \dots, 43/51$ do
 - ▶ If $i \equiv 0 \bmod Nk$ then
$$W[i] = W[i - Nk] \oplus SB(W[i - 1] \lll 8) \oplus RCON[i/Nk],$$
 - ▶ Otherwise $W[i] = W[i - 1] \oplus W[i - Nk],$

- ▶ AES-256 ($Nk = 8$):

- 1 Initialize $W[0, \dots, 7]$ with the user supplied key.
- 2 For $i = 8, \dots, 59$ do
 - ▶ If $i \equiv 0 \bmod Nk$ then
$$W[i] = W[i - Nk] \oplus SB(W[i - 1] \lll 8) \oplus RCON[i/Nk],$$
 - ▶ Else if $i \equiv 4 \bmod Nk$ then
$$W[i] = W[i - 8] \oplus SB(W[i - 1]),$$
 - ▶ Otherwise $W[i] = W[i - 1] \oplus W[i - Nk],$

Security Properties

- ▶ The S-boxes are based on inversion over $GF(2^8)$.
- ▶ The MixColumns operation is an MDS matrix, which along with the ShiftRows operation ensures full diffusion after two rounds.
- ▶ The “wide trail strategy” assures that the number of active S-boxes in any differential characteristic is at least five for two rounds, nine for three rounds, and 21 for four rounds.
- ▶ There structure offers some 4-round impossible differentials, and several sets of 4-round Square properties.

Differential/Linear Cryptanalysis

- ▶ The security against these attacks is derived from the fact that there are no good differentials (linear hulls) of high probability.

Differential/Linear Cryptanalysis

- ▶ The security against these attacks is derived from the fact that there are no good differentials (linear hulls) of high probability.
- ▶ In a series of papers, the maximal expected differential and linear probabilities for two and four rounds were computed.
- ▶ The results are that 4-round AES have no differentials or linear hulls with high enough probability for attacks.

- ▶ 1999 — Adaptive chosen plaintext and ciphertext attacks (boomerang attacks).

Current State of Affairs in Cryptanalysis

Time complexity of a related-key attack:

“Thus, the total time complexity of Step 2(b) is about $2^{256} \cdot 2^{167.0} = 2^{423.0}$ SHACAL-1 encryptions.”

- ▶ Most cryptanalytic papers discuss certificational attacks:
 - ▶ Data complexity — just slightly less than the entire code book.
 - ▶ Time complexity — just slightly less than exhaustive search.
 - ▶ Memory — store more information than there are particles in the universe

Current State of Affairs in Cryptanalysis (cont.)

- ▶ These certificational attacks are of great importance:
 - 1 Why to use a primitive whose less secure than optimal?

Current State of Affairs in Cryptanalysis (cont.)

- ▶ These certificational attacks are of great importance:
 - 1 Why to use a primitive whose less secure than optimal?
 - 2 By publishing the first step of analysis, others may be able to improve the attacks.
 - 3 Attacks only get better!

Current State of Affairs in Cryptanalysis (cont.)

- ▶ These certificational attacks are of great importance:
 - 1 Why to use a primitive whose less secure than optimal?
 - 2 By publishing the first step of analysis, others may be able to improve the attacks.
 - 3 Attacks only get better!
- ▶ But they do not help answering questions by users:
 - 1 Does this attack affect my system?
 - 2 Should I still use AES-256 for encryption?
 - 3 MD5 is still OK for certificates, right?

What a Break is?

- ▶ There is an ongoing debate what a broken scheme is.

What a Break is?

- ▶ There is an ongoing debate what a broken scheme is. Even from the theoretical point of view.
- ▶ The extreme approach: $\max(\text{Time}, \text{Data}, \text{Memory})$ less than Exhaustive search' time.
- ▶ Another approach: $(\text{Time}, \text{Data}, \text{Memory})$ better than generic attacks (time-memory-data tradeoff attacks).
- ▶ $\text{Time} \times \text{Memory} < \text{Exhaustive search}$.
- ▶ Money for finding a key in a given time $<$ for a generic attack.

What is a Practical Attack?

- ▶ We upper-bound the complexities of the attack.

What is a Practical Attack?

- ▶ We upper-bound the complexities of the attack.
- ▶ 2^{55} DES encryptions are feasible ...
- ▶ 2^{61} SHA-1 evaluations did not complete ...

What is a Practical Attack?

- ▶ We upper-bound the complexities of the attack.
- ▶ 2^{55} DES encryptions are feasible ...
- ▶ 2^{61} SHA-1 evaluations did not complete ...
- ▶ So, let's take 2^{64} cycles
 - ▶ which are about 2^{56} AES encryptions.
- ▶ This is also a restriction on the data complexity.

The Related-Key Model

- ▶ First introduced by Knudsen and Biham, independently.
- ▶ The adversary is assumed to have some knowledge on the relation.
- ▶ In 1996/7, the concept of related-key differentials was introduced, along with it, the concept where the adversary is allowed to chose the key relation.
- ▶ There are “good relations” (XORs, rotations, or additions), and “bad relations” (AND, ORs, XORs + additions together).

The Related-Key Model

- ▶ First introduced by Knudsen and Biham, independently.
- ▶ The adversary is assumed to have some knowledge on the relation.
- ▶ In 1996/7, the concept of related-key differentials was introduced, along with it, the concept where the adversary is allowed to chose the key relation.
- ▶ There are “good relations” (XORs, rotations, or additions), and “bad relations” (AND, ORs, XORs + additions together).
- ▶ At the end, the main issue is applicability — does the attack scenario allows this relation or not.

Example: Related-Key Differentials

- ▶ The probability of a regular differential is:

$$\Pr_{P,K}[E_K(P) \oplus E_K(P \oplus \Delta P) = \Delta C]$$

- ▶ The probability of a related-key differential is:

$$\Pr_{P,K}[E_K(P) \oplus E_{K \oplus \Delta K}(P \oplus \Delta P) = \Delta C]$$

- ▶ The key difference leads to subkey differences, that may be used to cancel the differences in the input to the round function.

The Related-Subkey Model

- ▶ This new model was recently introduced in [BK09].
- ▶ In related-key attacks, a simple relation R is used for the keys K_1, K_2 .
- ▶ In related-subkey attacks, R is a simple relation between two subkeys, RK_1, RK_2 .
- ▶ The two subkeys are then handled by the key schedule algorithm to obtain the actual keys.
- ▶ This slightly less intuitive approach (and less practical one) can be “covered” by the theoretical treatment by just expanding the set of “good relations”.

- 5 Summary

An Interesting Property of the Key Schedule Algorithm of AES-256

Our results are based on the fact that key difference

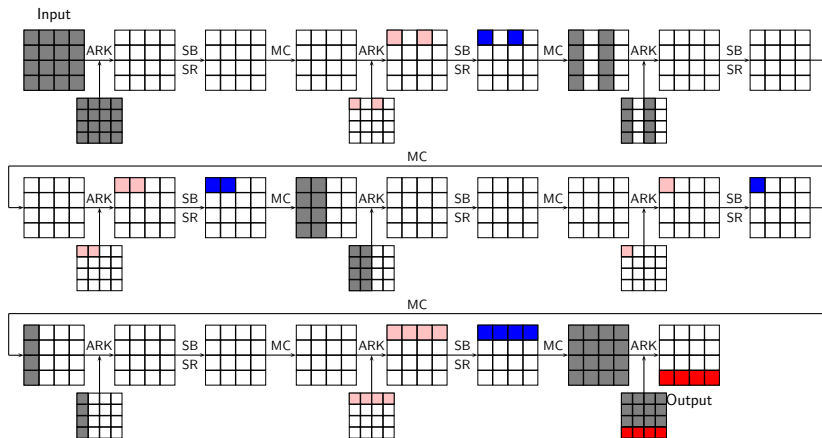

leads to the 10 subkey differences

With probability 1!

An 8-Round Related-Key Differential

The probability is 2^{-56} . It can be transformed into a truncated one predicting 24 bits of difference with probability 2^{-36} .

Verification of the Differential

- ▶ We have verified experimentally the correctness of the 7-round related-key differential derived from the 8-round one (it has probability 2^{-30}).
- ▶ We performed 100 experiments, each with a random key and 2^{32} random plaintext pairs.

Pairs	0	1	2	3	4	5	6
Theory	1.8	7.3	14.7	19.5	19.5	15.6	10.4
Experiment	0	10	18	10	28	18	6

Pairs	7	8	9	10	11	12
Theory	6.0	3.0	1.3	0.5	0.2	0.06
Experiment	8	1	0	0	0	1

A 10-Round Related-Subkey Differential

- ▶ In the related-subkey model, it is possible to pick two keys which satisfy the difference in a slightly different manner.
- ▶ The related-subkey allows for shifting the differential by one round.
- ▶ This allows an extension of the differential in the backwards direction (despite having a highly active state).
- ▶ Which in turn, allows for attacks of practical complexity of up to 10 rounds, and semi-practical of up to 11 rounds.

Other Attack Scenarios

- ▶ The attacks work when the plaintexts are generated not randomly as well.
- ▶ For example, when counter mode is used. The encryption system is initialized to two initial states and are allowed to generate data sequentially. This simplifies the attack model.
- ▶ The attacks are applicable when the plaintexts are ASCII characters (as some key differences are suitable).
- ▶ Or even when they are ASCII characters representing only numeric values.
- ▶ The minimal hamming weight of the key difference is 24.

- 5 Summary

Summary of the Attacks

Rounds	Scenario	Time	Data	Memory	Result
8	Key Diff. – CP	2^{31}	2^{31}	2	Distinguisher
8	Subkey Diff. – CC	$2^{26.5}$	$2^{26.5}$	$2^{26.5}$	35 subkey bits
9	Key Diff. – CP	2^{39}	2^{38}	2^{32}	Full key
9	Subkey Diff. – CC	2^{32}	2^{32}	2^{32}	56 key bits
10	Subkey Diff. – CP	2^{49}	2^{48}	2^{33}	Distinguisher
10	Subkey Diff. – CC	2^{45}	2^{44}	2^{33}	35 subkey bits
11	Subkey Diff. – CP	2^{70}	2^{70}	2^{33}	50 subkey bits

Security Implications

- ▶ Extending AES-128 key to 256 bits actually reduces security!
- ▶ The security margins of AES-256 are smaller than expected.
- ▶ The related-subkey model — many new results awaiting.

Security Implications

- ▶ Extending AES-128 key to 256 bits actually reduces security!
- ▶ The security margins of AES-256 are smaller than expected.
- ▶ The related-subkey model — many new results awaiting.
- ▶ This is a good time to check that Serpent-support. . .

Conclusions

- ▶ Did we break the full AES with practical complexity?
